

MULTI-LINE ADSL MODEM

PRIORITY

This application claims priority of Provisional US Patent application Serial Number 60/156,475 filed September 28, 1999.

CROSS REFERENCE TO RELATED APPLICATIONS

Cross reference is made to commonly assigned US Patent Application Serial No. _____ Attorney's Docket Number TI-28222 entitled "Multi-Client ADSL Modem" filed August 31, 2000, the teachings included herein by reference.

FIELD OF THE INVENTION

The present invention is generally related to communication networks, and more specifically to networks adapted to communicate over standard residential 2-wire phone lines including twisted pair loops adapted to support ADSL communications.

BACKGROUND OF THE INVENTION

Asymmetrical Digital Subscriber Lines (ADSL) is an ANSI standard identified as T1.413 issued in 1995 which presents the electrical characteristics of the ADSL signal as it should appear at a network interface. Generally, ADSL is a high-speed communication technology that allows one client modem, such as that at a remote terminal (RT), to be connected to only one central office (CO) modem through one twisted pair telephone line forming a loop. Typically, discrete multi-tone (DMT) modulation is the chosen line code technique standard in a typical ADSL system. Upstream communications, such as from RT to CO, and downstream

communications, such as CO to RT, are divided from one another using frequency division multiplexing (FDM) or using echo canceling, allowing the frequency band for upstream communications to be shared with downstream communications thereby increasing the overall data rate over the loop.

5

Disadvantageously, the ADSL standard allows only one pair of modems (CO and RT) to communicate over the loop at the same time. The CO modem may send a downstream signal while simultaneously receiving an upstream signal from the RT, frame by frame. Similarly, the RT modem may receive the downstream communication from the CO modem and

10 simultaneously send upstream communication signals to the CO modem.

Since the standardization of ADSL communications, there have been introduced varied implementations and customized uses of the ADSL technology, such as disclosed in commonly assigned US Patent 5,479,447 entitled "Method and Apparatus for Adaptive, Variable
15 Bandwidth, High-Speed Data Transmission of a Multi-Carrier Signal over Digital Subscriber Lines, the teachings of this patent included herein by reference.

As technology evolves and the world becomes more connected including providing access to high-speed internet devices, digital TV (DTV), and even high-definition TV (HDTV),
20 increased bandwidth will be required to connect such devices which may be located at a home or small office. Today, a single pair of twisted telephone line does not provide sufficient bandwidth to allow communications at the data rate required for some of these devices, which is about 20 Mbps for HDTV in the case of line conditioning. Although cable modems may be designed to reach up to 40 Mbps, there are many users that are required to share this data bandwidth. This
25 means that the 40 Mbps is the burst data rate for one user, or the maximum data rate for all users.

There is desired a higher bandwidth modem and communication network that provides for a higher data rate access than that provided by conventional ADSL modems operating over a single loop of twisted pair of telephone wire. Such an improved higher data rate communication
30 is desired to be compatible with ADSL standards, and which can support high speed

communications suitable for the internet, digital TV, and even HDTV.

SUMMARY OF THE INVENTION

5 The present invention achieves technical advantages as an improved modem,
communication network, and method of operation thereof that provides a much higher burst data
rate than standard ADSL technology without increasing the number of telephone lines. A multi-
line ADSL modem is provided that has connections to several ADSL modems at a central office
(CO) through a master loop, as well as through shared loops and/or broadcast loops. The master
10 loop provides the basic connection between the multi-line ADSL modem and the corresponding
CO modem while maintaining regular telephone service. By accessing and using the additional
shared loops, such as those serving other residential devices, the shared loop allows the multi-
line modem, preferably a multi-line ADSL modem, to share the transmission capacity of the
shared loop with other residential modems. Advantageously, the multi-line ADSL modem is
15 able to receive high speed broadband broadcast data from the central office when several loops
are configured as a broadcast loop such as for downstream transmission. Optionally, several
loops can also be configured for broadband upstream communication if desired.

BRIEF DESCRIPTION OF THE DRAWINGS

20 Figure 1 illustrates a block diagram of a 3-line ADSL system whereby a multi-line
modem has one master loop connection for itself, and also shares two other loops thereby
providing additional access capacity;

25 Figure 2 illustrates a multi-line ADSL system with a multi-line ADSL modem connected
to three pairs of loops with additional high-pass filters facilitating the use of the additional loops;

30 Figure 3 illustrates a single-user model in a multi-line ADSL system, the single user
model allowing a multi-line ADSL modem to share loops without other ADSL modems in
operation;

Figure 4 illustrates a multi-user model in a multi-line ADSL system, whereby the multi-user model allows a multi-line ADSL modem to share loops with other ADSL modems that are in operation; and

5

Figure 5 illustrates the broadcast model in a multi-line ADSL system, this broadcast model being a special multi-user model which allows a multi-line ADSL to, for instance, only listen to and receive the broadband communication from the broadcast loop.

10 DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to Figure 1, there is illustrated generally at 10 a communication network having a single residential multi-line modem 12 serving a remote terminal (RT) 13 and adapted to communicate with a corresponding central office (CO) modem 14 serving a communications terminal 15 at a central office 16 via a master loop 18 comprising a conventional twisted pair telephone line. Advantageously, the multi-line modem (RT) 12 is also adapted to share adjacent loops 20 and 22 connected to the common central office 16 and serving other residential customers which may be served by a single line modem 24, a multi-line modem 12, or just a Plain-Old-Telephone-System (POTS) device 26 such as phone set or fax machine.

20

As shown in Figure 1, the multi-line modem 12 is seen to be connected to the respective master loop 18, while also being connected through a high-pass filter 30 to each of the shared loops 20 and 22 to separate out low frequency communications, such as voice communications, resident on the shared loops from the multi-line terminal 12. As shown in Figure 1 the multi-line terminal 12 is connected to two other shared loops 20 and 22 serving nearby residential customers which are primarily served by different respective CO modems 14 located at the same and common central office 16. Although two additional shared loops are shown to be connected to the multi-line modem 12, it is envisioned that only one shared loop, or more than two shared loops, may be connected thereto depending on the desired bandwidth to be available to a customer served by the multi-line modem 12. As illustrated in Figure 1, the bandwidth of the

A2
Contd

communication between a user of multi-line modem 12 is increased at least threefold to provide a significantly greater burst data rate over a single loop.

5 Preferably, the multi-line modem 12, as well as the central office modems 14 are all capable of and adapted to communicate with each other in a format compatible with ADSL standards, as well as modifications thereto.

Sub
A3

Referring now to Figure 2, there is illustrated in more detail communication network 10 illustrating a frequency splitter 32 being provided for each standard user having both a customer premise network 34 and having a telephone set, voice-band modem or ISDN terminal 36. Advantageously, a frequency splitter 38 is provided to service the multi-line modem 12. Splitter 38 has a low pass filter 40 and high pass filter 42 servicing and connected to the master loop 18, whereby the low frequency signals are separated out by the low pass filter 40 to the telephone set, voice-band modem, or ISDN terminal 36, and the high pass filter 42 splitting the high frequency signals to the multi-line modem 12. An additional high pass filter 44 is provided in splitter 38 to separate out the high frequency signals of each of the shared loops 20 and 22 for communication to the multi-line modem 12. The high pass filters 42 and 44 provide the high frequency components of both the master loop 18 as well as the shared loops 20 and 22 such that they are all available via the multi-line receiver 12 to the high data rate customer premise network shown at 46.

Sub
A4

A corresponding splitter 50 is provided at the central office 16 at the opposing end of the respective loop to separate the low frequency signals via a low pass filter 52 to a narrowband network 54, and the high frequency signals via a high pass filter 56 to a broadband network 58. The combination of the splitters 50 and the corresponding splitters 32 and 38 direct the broadband network communications over the respective loops to the customer premise networks, with the communications of the narrowband networks communications being directed to the terminals 36 and 46. Advantageously, the high pass filters 42 and 44 separate out the low frequency voice band signals for the shared loop signals from minimum interference. The shared loops may be configured to serve a single line modem, or a multi-line modem, or simply a POTS

AA Cont.
device such as a phone set or fax machine. The respective high pass filters for the respective modem minimize the interference between the voice band signals and the ADSL band signals.

Sub AS
The multi-line receiver 12 advantageously shares one or more other loops serving other customer terminals, without causing interference with the respective voice band signals, such that the improved customer premise network 46 served by the multi-line modem 38 achieves a significantly higher data transmission rate than that achievable with only one twisted pair of conductors forming the master loop 18.

10 Referring now to Figure 3, there is depicted a single-user model 60 of the multi-line ADSL system with the multi-line modem 12 connected to the master loop 18, as well as to the shared loops 20 and 22 as shown in Figure 2. The master loop is shown to be connected to a respective ATU-C modem 14, and is adapted to simultaneously time share one or more of the adjacent loops 20 and 22 serving other terminals located in close proximity to modem 12 to
15 achieve the significantly higher data rate, such as 40 Mbps or more. According to the present invention, the shared loops 20 and 22 may be configured, such as at the multi-line modem 12, so as to provide only downstream communications from the respective CO modems 14 to the multi-line modem 12. Optionally, the communications may be set up for bi-directional broadband communications to facilitate expanded bandwidth communications for both upstream
20 and downstream communications.

Referring now to Figure 4, a multi-user model of a multi-line ADSL system is shown at 70. Each of the multi-line ATU-R modems 12 are seen to be connected to and communicate over a respective master loop 18, and at the same time each of these multi-line modems 12 is
25 configured to share one or more loops serving other modems 24 for achieving a higher data rate. The shared loops may be configured to provide to modem 12 downstream communications only, or providing both upstream and downstream bi-directional broadband communications. The master loop 18 is always set up and configured for both upstream and downstream communications.

The shared loops can be configured to share information in frames, known as time division, using different tones, known as frequency division, or using different codes known as code division. As shown, there are multiple multi-line modems 12 connected to share common shared loops in the multi-user mode.

5

Referring now to Figure 5, a broadcast model of a multi-line ADSL system 80 is shown. Each multi-line ATU-R modem 12 is seen to be connected to a respective master loop 18, and at the same time configured to time share one or more of the other adjacent loops shown at 20 for achieving a higher data rate than that achievable by communicating ADSL standard signals over just one loop. The shared loops 20 may be configured for downstream communications only, or to facilitate both upstream and downstream communications. The master loop 18 is typically set up for upstream and downstream communications all the time. Again, the shared loops can be shared in frames, (time division), tones (frequency division), or code division such as that similar to CDMA technology used in wireless networks. On the other hand, a broadcast service system 82 can integrate several shared loops into a broadcast service system and integrate several shared loops into a broadcast loop 84. Each of the multi-line modems 12 can receive the broadcast data from the broadcast loop 84 with or without a master loop connected to the dedicated modems 12.

In summary, the present invention achieves technical advantages as an improved multi-line modem and network, and method of using the same, whereby the improved modem communicates over both a master loop and adjacent shared loops to achieve significantly higher data rates so as to facilitate use of high data rate devices including internet communications, digital video and HDTV communication signals. No additional loops are required to be installed as a multitude of twisted pair conductor loops are already installed providing communications between the central office (CO) and the plurality of adjacent customers served by a common central office. The present invention takes advantage of the ADSL standard communications which are well suited for communication over these twisted pair loops. The multi-line modem 12 is specifically configured to share the adjacent shared loops and handle the bi-directional communications as a transceiver between the loops and the customer premise network. The multi-line modem 12 has appropriate hardware and/or software to split high data rate upstream

communications from the served customer premise network to the appropriate loops providing a higher bandwidth than that provided by a single loop. Likewise, the multi-line modem 12 is adapted to combine the received downstream communications from each of the respective loops to form a single high data rate signal which is provided to the served customer premise network

5 46. Again, communications over each of the loops is configured to be compatible with ADSL standards, while the communication signal provided to the customer premise network may be configured to be compatible with any number of standards including high definition television (HDTV), digital video and high speed internet access. The present invention is a low cost high bandwidth network which does not require the installation of any additional loops or the upgrade
10 thereof while achieving a high data rate communication network.

Though the invention has been described with respect to a specific preferred embodiment, many variations and modifications will become apparent to those skilled in the art upon reading the present application. It is therefore the intention that the appended claims be interpreted as
15 broadly as possible in view of the prior art to include all such variations and modifications.
